

QUASAR ELECTRONICS KIT No. 1035

SPACE SOUND EFFECTS

General Description

Another interesting project from Quasar Electronics Kit that will let you create an infinite variety of electronic sounds similar to those we have come to associate with space travel because of their extensive use in movies and arcade games.

Technical Specifications – Characteristics

Working voltage: 12V DC

Max. current: 40 mA

How it Works

The circuit uses the CD4001 IC which has four NOR gates in one chip. The gates are connected as inverters and are used in pairs to form two oscillators, one having a fixed frequency and another which is variable and is used to modulate the first. Depending on the ratio of the two frequencies which is continuously variable, at the output of the circuit will appear a signal which will be the combination of the two frequencies, and that is usually a quite complex sound. The frequency of the variable oscillator is controlled by the setting of P1 which also controls the sound effect. The supply voltage is 12 VDC and is connected across the points 1 (+) and 2 (-) of the circuit. The output level is 1 V and is taken from point 5 (signal) and 4 (common).

Construction

First of all let us consider a few basics in building electronic circuits on a printed circuit board. The board is made of a thin insulating material clad with a thin layer of conductive copper that is shaped in such a way as to form the necessary conductors between the various components of the circuit. The use of a properly designed printed circuit board is very desirable as it speeds construction up considerably and reduces the possibility of making errors. Quasar Electronics Kit boards also come pre-drilled and with the outline of the components and their identification printed on the component side to make construction easier. To protect the board during storage from oxidation and assure it gets to you in perfect condition the copper is tinned during manufacturing and covered with a special varnish that protects it from getting oxidised and also makes soldering easier. Soldering the components to the board is the only way to build your circuit and from the way you do it depends greatly your success or failure. This work is not very difficult and if you stick to a few rules you should have no problems. The soldering iron that you use must be light and its power should not exceed the 25 Watts. The tip should be fine and must be kept clean at all times. For this purpose come very handy specially made sponges that are kept wet and from time to time you can wipe the hot tip on them to remove all the residues that tend to accumulate on it. DO NOT file or sandpaper a dirty or worn out tip. If

the tip cannot be cleaned, replace it. There are many different types of solder in the market and you should choose a good quality one that contains the necessary flux in its core, to assure a perfect joint every time.

DO NOT use soldering flux apart from that which is already included in your solder. Too much flux can cause many problems and is one of the main causes of circuit malfunction. If nevertheless you have to use extra flux, as it is the case when you have to tin copper wires, clean it very thoroughly after you finish your work. In order to solder a component correctly you should do the following:

Clean the component leads with a small piece of emery paper.

- Bend them at the correct distance from the component's body and insert the component in its place on the board.
- You may find sometimes a component with heavier gauge leads than usual, that are too thick to enter in the holes of the p.c. board. In this case use a mini drill to enlarge the holes slightly.
- Do not make the holes too large as this is going to make soldering difficult afterwards.
- Take the hot iron and place its tip on the component lead while holding the end of the solder wire at the point where the lead emerges from the board. The iron tip must touch the lead slightly above the p.c. board.
- When the solder starts to melt and flow wait till it covers evenly the area around the hole and the flux boils and gets out from underneath the solder. The whole operation should not take more than 5 seconds. Remove the iron and allow the solder to cool naturally without blowing on it or moving the component. If everything was done properly the surface of the joint must have a bright metallic finish and its edges should be smoothly ended on the component lead and the board track. If the solder looks dull, cracked, or has the shape of a blob then you have made a dry joint and you should remove the solder (with a pump, or a solder wick) and redo it.
- Take care not to overheat the tracks as it is very easy to lift them from the board and break them.
- When you are soldering a sensitive component it is good practice to hold the lead from the component side of the board with a pair of long-nose pliers to divert any heat that could possibly damage the component.
- Make sure that you do not use more solder than it is necessary as you are running the risk of short-circuiting adjacent tracks on the board, especially if they are very close together.
- When you finish your work cut off the excess of the component leads and clean the board thoroughly with a suitable solvent to remove all flux residues that may still remain on it.

The IC used in this project is of the CMOS type and as you probably know these devices are quite easily damaged by static electricity. Even touching them with the fingers can sometimes destroy them. Apart from the extra care needed when you handle the IC this project should present no other difficulty. As usually, start building the circuit by soldering the IC socket and the pins on the PC board, following them with the resistors, the trimmer and the capacitors. The electrolytic capacitors have a negative and a positive pole which are also marked on the board accordingly to indicate the correct position of the leads.

When all the components have been soldered on the p.c. board, make a careful visual inspection for short circuits or other mistakes, clean the p.c. board from flux residues and insert the IC in its socket. This operation requires a bit of extra care as incorrect handling can destroy the component. The IC should be taken out of the aluminium foil wrapper just before insertion and the board AND your body should be grounded to discharge static.

Even though everything may be grounded try to avoid any contact with the pins of the IC till it has been inserted in its socket. Connect the circuit across a suitable power supply of

12 VDC at points 1 (+) and 2 (-) and use it output signal (points 5 signal & 4 common) to drive an amplifier. Turning the trimmer P1 should produce an infinite variety of electronic sounds.

Adjustments

This kit does not need any adjustments, if you follow the building instructions.

Warning

Quasar Electronics kits are sold as stand alone training kits.

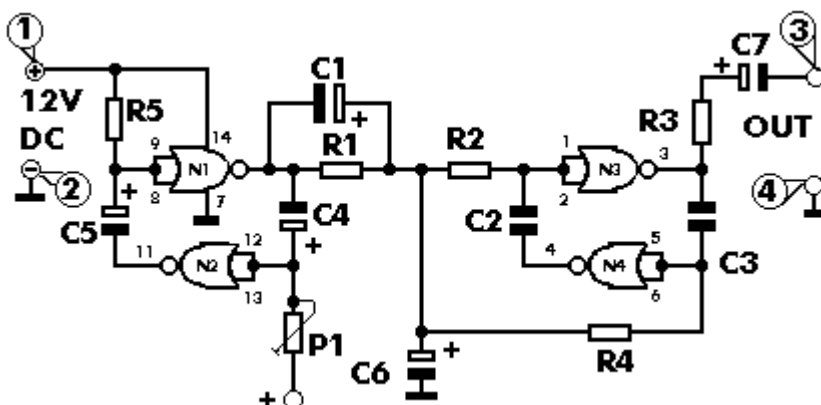

If they are used as part of a larger assembly and any damage is caused, our company bears no responsibility.

While using electrical parts, handle power supply and equipment with great care, following safety standards as described by international specs and regulations.

If it does not work

- Check your work for possible dry joints, bridges across adjacent tracks or soldering flux residues that usually cause problems.
Check again all the external connections to and from the circuit to see if there is a mistake there.
 - See that there are no components missing or inserted in the wrong places.
 - Make sure that all the polarised components have been soldered the right way round.
Make sure that the supply has the correct voltage and is connected the right way round to your circuit.
 - Check your project for faulty or damaged components.
- If your project still fails to work, please contact us for information about our Get-You-Going service.
